Mustafa<sup>\*\*</sup> and EL-Shal, M.H.<sup>\*\*</sup> <sup>\*</sup> Agronomy Department, Faculty of Agriculture, Moshtohor, Benha University, Egypt. <sup>\*\*</sup> National Gene Bank and Genetic resources, Agricultural Research Center, Giza, Egypt.

### ABSTRACT

A half diallel cross among eight parents of wheat (Triticum aestivum L.) was evaluated under recommended irrigation and drought stress in RCBD with three replications. Mean squares for genotypes, parents, crosses and parent vs. crosses were significant for the most measurements in both irrigation treatments as well as the combined analysis. The highest mean values were detected under stress condition and combined analysis by parents  $P_4$ ,  $P_6$ ,  $P_{8}$ ,  $P_{7}$ ,  $P_{1}$  and  $P_{8}$  for stomatal conductance (SC), net photosynthesis rate (Pn), protein percentage, ash percentage, carbohydrate percentage and grain yield/plant, respectively. Meanwhile, the highest mean values were recorded under stress condition and combined analysis with crosses  $P_1 x P_6 P_5 x P_8$ ,  $P_3 x P_4 P_3 x P_4$  and  $P_2 x P_5$  for stomatal conductance (SC), net photosynthesis rate (Pn), protein percentage, ash percentage, carbohydrate percentage and grain yield/plant, respectively. Superiority percentage relative to check variety Sahel 1 for grain yield/plant was obtained by crosses; P<sub>2</sub> x P<sub>5</sub>, P<sub>2</sub> x P<sub>4</sub>, P<sub>2</sub> x P<sub>7</sub>, P<sub>1</sub> x  $P_3$ ,  $P_3 \times P_6$  and  $P_5 \times P_7$  under normal and stress irrigations and for the combined analysis. The mean squares were significant for the most measurements in both irrigation treatments as well as the combined analysis for general combining ability (GCA) and specific combing ability (SCA). GCA/SCA ratio, which exceeded the unity was obtained for LT, protein percentage, carbohydrate percentage, ash percentage and grain yield/plant in both irrigations treatments and the combined analysis. For chemical measurements (protein, carbohydrate and ash percentages) and grain yield/plant the ratio of SCA x I/SCA was much higher than the ratios of GCA x I/GCA. The parental lines  $P_1$ ,  $P_2$  and  $P_3$  for SC and  $P_5$ ,  $P_6$ and  $P_7$  for grain yield/plant, exhibited significant positive " $\hat{g}_i$ " effects under stress

irrigation treatment. The most desirable " $S_{ij}$ " effects were recorded by the cross  $P_3 \times P_4$ under stress irrigation for LT, TR, Pn and carbohydrate percentage,  $P_1 \times P_5$  and  $P_4 \times Gem.9$ in the combined analysis for stomatal conductance;  $P_4 \times P_5$  and  $P_5 \times P_8$  under normal, stress irrigation treatments and the combined analysis for protein percentage.

Key words: Triticum aectivum, General combining ability (GCA), Specific combining ability (SCA), Heterosis, Drought, Wheat, Randomized Complete Block Design(RCBD).

### **INTRODUCTION**

Wheat (*Triticum aestivum* L.) is the most important cereal crop in Egypt. Increasing wheat production to narrowing the gap between production and consumption is considered the main goal in Egypt as well as in most countries all over the world. Differential characterization between Egyptian old varieties genetic resources in different geographical regions, represent an important genetic resource that can be used to improve modern varieties by introducing new alleles or combinations of genes. The old varieties may include genetic sources of biotic and a

biotic stress resistance, quality, yield and resistance genes to drought, especially in environments not tested in major breeding programs. Drought is a worldwide issue that impacts seriously on the security of food production. Global climate change makes this even worse (Elisabeth *et al.* 2009). The increase in stomatal resistance under water stress condition was due to the stomatal closure Bousba *et al.* (2009) and Changhai *et al.* (2010). A high net photosynthesis rate is considered to be one of the most important breeding strategies for better adaptation to stressful environments (Austin *et al.* 1980 and Austin 1989). The photosynthetic activity of flag leaves is especially important during grain filling when the older leaves begin senescing (Loss and Siddique 1994, Turner 1997). The main objectives of the present investigation are to assess the variations among wheat genotypes and available crosses for drought tolerance characters, to estimate the magnitude of superiority, general combining ability (GCA) and specific combining ability (SCA) to improve wheat under drought conditions and to determine suitable measurements for drought resistance in wheat genotypes.

### MATERIALS AND METHODS

The breeding materials used herein included eight parents i.e. five promising landraces (P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>, P<sub>4</sub> and P<sub>5</sub>) for drought tolerant selected by National Gene Bank and Genetic Resources according to IPGRI (International of Plant Genetic Resources Institute) descriptor and three cultivars wheat (Gemmeiza 9 (P<sub>6</sub>), Sahel 1 (P<sub>7</sub>) and Yacora Kojo (P<sub>8</sub>)). In 2008/2009 growing season, in Sids Agricultural Research Station, grain from each of the eight parental genotypes were sown at various planting dates in order to overcome the differences in time of heading during this season. All possible cross combinations (without reciprocals) were made among the eight genotypes, giving seeds of  $F_1$  28 crosses. In 2009/2010 season, two experiments were conducted at Al-Gemmeiza Agricultural Research Station, Gharbia Governorate, Egypt. Each experiment included the eight parents and their 28 possible crosses in a randomized complete block design (RCBD) with three replications. The planting date was 24<sup>th</sup> of November. The first experiment was irrigated only two irrigations (sowing irrigation and next one after 25 days) after which irrigation was stopped till the end of the season. The second experiment was normally irrigated by giving the recommended number of irrigations (5). Each plot consisted of one row, of 1.5 meters long and 30cm wide. Grains were individually sown in hills at 20cm space between plants within row. The other cultural practices of growing wheat were properly practiced. Data were recorded from each plot for physiological traits; leaf temperature  $({}^{0}C)$ , transpiration rate (milimol/m<sup>2</sup>/s), stomatal conductance (milimol/ $m^2/s$ ) and net photosynthesis rate ( $\mu$ mol/ $m^2/s$ ). All data for physiological measurements have been taken by the CI-340 Ultra-Light Portable Photosynthesis System.

Chemical analysis; protein, carbohydrate and ash percentages were determined by near infra analyzer (NIR) (g/100g of the seeds) according to Zhao *et al.* (2004). Data for grain yield/plant (gm) yield was recorded on ten guarded plants chosen at random from each plot. Normal performance plants were obtained in all hybrids except those of the two crosses ( $P_3xP_4$  and  $P_4xP_8$ ) where all plants were subjected to partial necrosis phenomenon. The decrease of yield was detected in both crosses. Monthly average temperature and amount of rainfall and mechanical and chemical analysis of experimental soil are shown in Table (1) and (2).

month no.	Max. Temperature (°C)	Min. Temperature (°C)	Max Relative Humidity (%)	Min Relative Humidity (%)	Wind Speed (m/s)	Rainfall rate

The obtained data were statistically analyzed using computer statistical program MSTAT.C. General and specific combining ability estimates were estimated according to Griffing's (1956) diallel cross analysis designated as method 2 model 1 for each experiment. The combined analysis of two experiments was carried out whenever homogeneity of error variance was detected (Gomez and Gomez, 1984). Superiority of grain yield was calculated for individual cross as the percentage deviation of  $F_1$  mean performance from check variety Sahell average value.

### **RESULTS AND DISCUSSION**

### **Drought measurements**

Mean squares for leaf temperature during flower (LT), net photosynthesis rates (Pn), transpiration rate during flower (TR) and stomatal conductive during flower (SC), protein percentage, carbohydrate percentage, ash percentage and grain yield/plant for each of normal and stress environments as well as the combined analysis are presented in table (3).

Mean squares for genotypes, parents, crosses and parent vs. crosses were found to be significant for the eight measurements in both irrigation treatments as well as the combined analysis except genotype mean square and its components for LT in stress condition , parent mean square for LT in separate environments as well as the combined data, cross mean square for LT in stress condition and TR in stress condition, and parent vs. crosses for ash percentage in both environmental and the combined analysis , Pn and SC in stress and combined analysis and non-stress conditions, respectively, indicating that wide diversity between the parental used in the present study for these traits. Genotypes x irrigation, parent x irrigation,  $F_1$  x irrigation and parent vs. cross x irrigation for LT and Pn and parent vs. crosses x irrigation for TR, Pn, carbohydrate and ash percentage. Such results indicated that the tested genotypes varied from one to anther and ranked differently from normal to stress irrigation treatments.

Results in table (4) showed the average of drought and chemical measurements at both irrigation treatments. It is clear that LT, SC, protein and ash percentage increased significantly with stress compared with non-stress condition. While, the Pn, TR and carbohydrate percentage decreased significantly to stress compared with non-stress conditions, indicating that selection for stress tolerance should gave a positive yield response under stress. Also, the results indicated that selection under irrigated environment would be less effective for improving grain yield under drought stress than direct selection in the stress condition, Atlin and Frey (1989) demonstrated that grain yield in stress or low- productively environments were not controlled by same genes, making indirect selection unattractive. The result also indicated that mean values of normal environment for yield and its components were high than these of stress condition.

### **Mean performances**

The results in table (4) clearly show that during occurrence of water stress, stomatal conductance (SC) increased considerable. The highest mean values of SC under stress condition were recorded with parent  $P_4$  followed by  $P_2$  and then by  $P_7$  (Sahel<sub>1</sub>). Meanwhile, the lowest values recorded with P<sub>5</sub> followed by P<sub>3</sub> and P<sub>6</sub> (Gemmeiza<sub>9</sub>). Also, the highest values were obtained from crosses P<sub>1</sub> x P<sub>6</sub> followed by P<sub>1</sub> x P<sub>8</sub> and P<sub>3</sub> x P<sub>5</sub>, meanwhile, the lowest SC was obtained with P<sub>3</sub> x P<sub>4</sub>, P<sub>5</sub> x P<sub>6</sub>, P<sub>1</sub> x P<sub>4</sub>, P<sub>2</sub> x P<sub>3</sub> and P<sub>1</sub> x P<sub>7</sub>. Seropian and Planchon (1984), Mahgoub (1996), Bousba et al. (2009) and Changhai et al. (2010) mentioned that, the increase in stomatal resistance under water stress condition was due to the stomatal closure. This is commonly found in many species and may indicate a control of stomatal conductance through hydraulic feedback mechanism (Giorio et al. 1999). Moreover (West et al. 1990) showed that, the drought resistance cultivar had a significant higher stomatal resistance plants closed their stomata in response to the slight water stress condition, while the drought sensitive plants kept their stomata open. Shimshi and Ephart (1975), who worked with up to 11 cultivars of spring wheat grown under field conditions, suggested that the porometer method would be useful in wheat breeding programs. The study showed that SC was the best method to use screen plants for drought resistance.

Low soil moisture content decreased the (Pn) in wheat; Aminian *et al.* (2010) studied photosynthesis rate and the relationship with grain yield in wheat under water-stressed and well-watered conditions. Correlation coefficient indicated that photosynthesis rate was most important in affecting yield under the both experiments. The highest mean values of (Pn) for parental lines were Gemm.9 (P<sub>6</sub>) and Sahel 1(P<sub>7</sub>) followed by P<sub>2</sub> at normal, stress irrigation treatments as well as the combined analysis. Meanwhile, the lowest values were obtained by P<sub>5</sub> at both irrigation treatments and the combined data. Also, the greatest values were recorded by crosses P<sub>5</sub> x P<sub>8</sub>, P<sub>4</sub> x P<sub>5</sub> and P<sub>4</sub> x P<sub>6</sub> at normal irrigation, P<sub>3</sub> x P<sub>6</sub> and P<sub>5</sub> x P<sub>8</sub> at stress irrigation, P<sub>5</sub> x P<sub>8</sub> and P<sub>4</sub> x P<sub>5</sub> at the combined analysis. Stomatal closure increases the resistance to CO<sub>2</sub> diffusion into the leaf. An inhabitation of chloroplast activity low leaf temperature decreases the capacity to fix CO<sub>2</sub>. The stomatal conductance might play an important role in the high Pn under well watered or mid drought stress, but under severe drought stress the high Pn is related more to the maintenance of a higher capacity for mesophyll photosynthesis (Johson *et al.* 1984 and Inoue *et al.* 2004).

The parental variety Yacora ( $P_8$ ) expressed the highest values of protein percentage and ranked the second of the tested parents for ash percentage and it gave the lowest values for carbohydrate percentage at both irrigation treatments as well as the combined analysis.

Sahel 1 ( $P_7$ ) recorded the highest mean values for ash percentage at both treatments as well as the combined, while, Gemm.9 ( $P_6$ ) had the highest values for protein percentage at stress irrigation. The lowest mean values were recorded by ( $P_1$ ) for ash percentage and protein percentage at both irrigation treatments and the combined analysis, while, it recorded the highest one for carbohydrate percentage.

For protein percentage, the mean values of crosses ranged from 7.25, 9.04 and 8.15 by  $P_1$  x  $P_4$  and 13.81, 16.13 and 14.97 by  $P_3$  x  $P_4$  at normal, stress irrigation as well as the combined analysis. Also, the cross  $P_1$  x  $P_4$  recorded the highest values of carbohydrate percentage (73.40, 69.00 and 71.20). Meanwhile, the cross  $P_3$  x  $P_4$  gave the lowest values for this trait (62.93, 60.43 and 61.68%). Moreover, the cross  $P_1$  x  $P_2$  recorded the lowest values of ash percentage (0.32, 0.49 and 0.41%). While, the cross  $P_3$  x  $P_4$  gave the highest values (1.16 and 0.99) under stress irrigation and the combined analysis and cross  $P_6$  x  $P_7$  at normal irrigation.

It can be noticed from the above results, that there were significant increase of protein, carbohydrate and ash percentage exhibited to water stress. In this respect Kramer (1983) recorded that, carbohydrate and protein metabolism are disturbed under water deficit and this often leads to accumulation of sugar and amino acids.

For grain yield /plant, the parental variety Gemmeiza 9 ( $P_6$ ) had the lowest mean value at normal, stress irrigation treatments as well as the combined analysis, while the parental variety (Yacora)  $P_8$  recorded the greatest values at stress irrigation treatment and the combined analysis. The cross  $P_2 \ge P_5$  had the highest mean value at normal, stress irrigation treatments as well as the combined analysis. While, the cross  $P_3 \ge P_4$  had the lowest mean values and of this trait.

### Heterois

Superiority expressed as the percentage deviation of  $F_1$  mean performance from sahel 1at both irrigation treatments as well as the combined analysis are presented in table (4).

Twenty two, twenty one and twenty two hybrids exhibited significant superiority heterotic effects relative to check variety Sahel 1 in normal, stress irrigation treatments and for the combined analysis, respectively. The crosses;  $P_1 \times P_3$ ,  $P_1 \times P_5$ ,  $P_1 \times P_7$ ,  $P_2 \times P_3$ ,  $P_2 \times P_5$ ,  $P_2 \times P_7$ ,  $P_3 \times P_6$  and  $P_5 \times P_7$  gave the highest heterotic effects in both irrigation treatments and for the combined analysis.

### **Combining ability**

The mean squares associated with general combining ability (GCA) and specific combing ability (SCA) were found to be significant for all drought measurements in both irrigation treatments as well as the combined analysis except GCA and SCA for LT in stress irrigation and GCA for TR in stress condition table(3). It is evident that non-additive type of gene action was more important part of the total genetic variability for TR in stress irrigation. For the other studied drought measurement, both additive and non-additive gene effects were involving in determining the performance of single cross progeny. Also, when GCA/SCA ratio was used, it was found that Pn, TR and SC in both irrigation treatments as well as the combined analysis, exhibited low GCA/SCA ratio of less than unity, indicating the predominance of non-additive gene action in the inheritance of such traits. While, high GCA/SCA ratio, which exceeded than unity was obtained for LT, protein, carbohydrate, ash percentages and grain yield/plant in both treatments and the combined analysis. These results were along the same line of Abul-Naas et al. (2000) for the three measurements (i.e) LT, SC and TR. EL Seidy et al. (2009) showed that high GCA/SCA variance ratios which exceeded the unity and suggested that selection based on phenotype could be effective to improve and develop wheat genotypes. Muhammad and Ihsan 2009, Moussa and Morad 2009, mentioned that the GCA/SCA ratio exceeded the unity for most characters studied indicating that additive genetic variance was predominantly controlling the inheritance of these traits.

It is fairly evident that the ratios for GCA x I/GCA much higher than ratios of SCA x I/SCA. Such results indicated that additive effects were much more influenced by the environmental conditions than the non- additive genetic ones for these traits. On the other hand, the chemical measurements (protein, carbohydrate and ash percentages) and grain yield/plant the ratio of SCA x I/SCA was much higher than the ratios of GCA x I/GCA was detected. Such results indicated that non additive effects were much more influenced by environmental changes than GCA. El Hosary *et al.* (2009a, b) found that non additive type of gene action was much more influence by the environmental condition than additive genetic ones for some drought measurements.

### General combining ability effects

General combining ability effects " $\hat{g}_i$ " of each parent for all studied measurements at normal, stress irrigation as well as the combined analysis are presented in table (6). Such results are being used to compare the average performance of each parent with other genotype and facilitate selection of parents for further improvement to drought resistance. High positive values would be interest under all measurements in question except LT and TR where, high negative effects would be useful from the breeder point of view.

The parental line P<sub>1</sub> exhibited significant positive " $\hat{g}_i$ " effects for carbohydrate percentage in irrigation treatments as well as the combined analysis and SC under drought condition. However, it gave significant undesirable or insignificant " $\hat{g}_i$ " effects for other measurements. The parental line (P<sub>2</sub>) expressed significant positive " $\hat{g}_i$ " effects for SC and grain yield/plant in both irrigation treatments and the combined analysis and net photosynthesis rate under drought condition. While, it gave significant negative or insignificant " $\hat{g}_i$ " effects for other drought treatments. The parental line (P<sub>3</sub>) expressed significant positive " $\hat{g}_i$ " effects for protein percentage in both irrigation treatments and the combined analysis, stomatal conductance under control and carbohydrate percentage under drought condition and the combined analysis. However, it gave significant undesirable or insignificant " $\hat{g}_i$ " effects for other measurements. The parental line (P<sub>4</sub>) showed significant positive " $\hat{g}_i$ " effects for protein percentage in both irrigation treatments and the combined analysis; however, it gave either significant negative or insignificant " $\hat{g}_i$ " effects for other traits. The parental line (P<sub>5</sub>) had significant positive " $\hat{g}_i$ " effects for grain yield/plant in both irrigation treatments and the combined analysis and TR under normal irrigation, while it expressed insignificant " $\hat{g}_i$ " effects for the most other traits. The parental variety Gemm.9 (P<sub>6</sub>) expressed significant desirable " $\hat{g}_i$ " effects for SC, protein percentage, ash percentage and grain yield/plant in both irrigation treatments and the combined analysis. While, it gave insignificant " $\hat{g}_i$ " effects for the most traits. The parental variety Sahel 1 (P7) seemed to be good general combiner for ash percentage and grain yield/plant in irrigation treatments as well as the combined analysis and Pn in normal irrigation and the combined analysis. While, it gave significant undesirable or in significant " $\hat{g}_i$ " effects for other traits. The parental variety Yacora (P<sub>8</sub>) expressed significant positive " $\hat{g}_i$ " effects for protein percentage in irrigation treatments as well as the combined analysis and ash percentage under drought conditions and the combined analysis. Also, it gave either significant negative or insignificant " $\hat{g}_i$ " effects for other traits.

### Specific combining ability effects:

Specific combining ability effects " $S_{ij}$ " of the parental combinations were computed for all the studied measurements under normal, stress irrigation treatments and the combined analysis (Table 7).

The two crosses  $P_3 \ge P_5$  and  $P_{3} \ge P_7$  expressed significant desirable " $S_{ij}$ " effect for leaf temperature; ten, five and seven crosses, for transpiration rate; eleven, six and nine crosses for stomatal conductance; seven, seven and four hybrids, for Pn; eleven, twelve and thirteen crosses for protein percentage; twelve, twelve and thirteen crosses, for carbohydrate percentage; eight, seven and seven for ash percentage in normal, stress irrigation treatments as well as the combined analysis, respectively.

The most desirable " $\hat{S}_{ij}$ " effects were recorded by the cross namely P<sub>3</sub> x P<sub>5</sub> in the combined analysis and P<sub>3</sub> x P<sub>7</sub> under normal irrigation, P<sub>1</sub> x P<sub>4</sub> and P<sub>3</sub> x P<sub>4</sub> under stress irrigation and P<sub>1</sub> x P<sub>4</sub> and P<sub>3</sub> x P<sub>4</sub> in the combined analysis for transpiration rate, P<sub>4</sub> x P<sub>6</sub> and P<sub>5</sub> x P<sub>8</sub> under normal irrigation and P<sub>1</sub> x P<sub>5</sub> and P<sub>4</sub> x P<sub>6</sub> in the combined analysis for stomatal conductance; P<sub>4</sub> x P<sub>5</sub> and P<sub>5</sub> x P<sub>8</sub> under normal, stress irrigation and the combined analysis for Pn; P<sub>3</sub>x P<sub>4</sub>, P<sub>1</sub> x P<sub>6</sub> and P<sub>1</sub> x P<sub>8</sub> under normal, stress irrigation and the combined analysis for protein percentage; P<sub>1</sub> x P<sub>4</sub> and P<sub>3</sub> x P<sub>8</sub> in normal, stress treatments and the combined analysis for carbohydrate percentage and P<sub>3</sub> x P<sub>4</sub> in both irrigation treatments and the combined analysis and P<sub>1</sub> x P<sub>5</sub>, P<sub>1</sub> x P<sub>6</sub> and P<sub>1</sub> x P<sub>8</sub> under normal, stress and the combined analysis and P<sub>1</sub> x P<sub>5</sub>, P<sub>1</sub> x P<sub>6</sub> and P<sub>1</sub> x P<sub>8</sub> under normal, stress and the combined analysis and P<sub>1</sub> x P<sub>5</sub>, P<sub>1</sub> x P<sub>6</sub> and P<sub>1</sub> x P<sub>8</sub> under normal, stress and the combined analysis for protein percentage and P<sub>3</sub> x P<sub>4</sub> in both irrigation treatments and the combined analysis and P<sub>1</sub> x P<sub>5</sub>, P<sub>1</sub> x P<sub>6</sub> and P<sub>1</sub> x P<sub>8</sub> under normal, stress and the combined analysis, respectively for ash percentage. The mentioned combinations might be of interest in breeding programs aimed at producing pure line varieties as most combinations involved at least one good combiner.

Regarding grain yield/plant, sixteen, seventeen and seventeen parental combinations expressed significant positive " $\hat{S}_{ij}$ " effects under the normal, stress irrigation and the combined data, respectively. The meantime, the most desirable " $\hat{S}_{ij}$ " effects were recorded by the crosses P<sub>1</sub> x P<sub>5</sub>, P<sub>2</sub> x P<sub>4</sub>, P<sub>2</sub> x P<sub>5</sub>, P<sub>4</sub> x P<sub>6</sub>, P<sub>5</sub> xP<sub>7</sub>, P<sub>5</sub> x P<sub>8</sub> and P<sub>6</sub>x P<sub>8</sub> in both irrigation treatments as well as the combined data. From such results, it could be concluded that the crosses P<sub>3</sub> x P<sub>4</sub>, P<sub>1</sub> x P<sub>5</sub>, P<sub>4</sub> x P<sub>5</sub>, P<sub>4</sub> x P<sub>6</sub> and P<sub>5</sub> x P<sub>8</sub> were prospective in wheat breeding program since they expressed the highest " $\hat{S}_{ij}$ " effects for most studied physiological and chemical traits.

### تقيم الهجن التبادلية في القمح تحت ظروف الجفاف علي عبد المقصود الحصري \* - محمود الزعبلاوي البدوي \* - أحمد كمال مصطفي أحمد \*\* - محمد حلمي الشال \*\* \* قسم المحاصيل - كلية الزراعة بمشتهر - جامعة بنها \*\* البنك القومي للجينات والموارد الوراثية

تهدف الدراسة إلى تقييم قمح الخبز في تجربتين الاولى تحت ظروف الري العادي والثانية تحت ظروف الاجهاد المائي في ثلاث مكررات. كان التباين الراجع للتراكيب الورثية ، الهجن والتفاعل بين الأباء والهجن معنويا لكل من درجة حرارة الورقة، صافى التمثيل الضوئي، معدل النتح، مقاومة الثغور، نسبة البروتين، نسبة الكربو هيدرات و نسبة الرماد ومحصول الحبوب/نبات تحت ظروف الري الطبيعي (الكنترول)، الإجهاد الرطوبي والتحليل المشترك. أظهرت كلا من السلالات الأبوية P4 وP6 و P8 و P7 وP1 أعلى قيم لصفات مقاومة الثغور وصافى التمثيل الضوئي ونسبة البروتين% والرماد% و الكربوهيدرات% ومحصول الحبوب للنبات على الترتيب تحت ظروف الإجهاد المائي والتحليل المشترك. كما أظهرت الهجن P1 x P6 وP5 x P4 وP3 x P4 و P2 x P5 وP3 x P4 أعلى قيم لصفات مقاومة الثغور وصافى التمثيل الضوئي ونسبة البروتين% والرماد% و الكربو هيدر ات% ومحصول الحبوب للنبات على الترتيب تحت ظروف الإجهاد المائي والتحليل المشترك. كان التباين الراجع للقدرة العامة (GCA) والخاصة على الإئتلاف (SCA) معنويا في الصفات تحت الدر اسة. كانت النسبة بين القدرة العامة/القدرة الخاصة أعلى من الوحدة لصفات: درجة حرارة الورقة، نسبة البرتين، نسبة الكربوهيدرات و نسبة الرماد تحت ظروف الري الطبيعي (الكنترول)، الإجهاد الرطوبي والتحليل المشترك. بينما كانت النسبة بين القدرة العامة/القدرة الخاصة لمعدل النتح و مقاومة الثغور وصافي التمثيل الضوئي أقل من الوحدة تحت ظروف الري الطبيعي (الكنترول)، الإجهاد والتحليل المشترك. كانت النسبة بين القدرة الخاصة وتفاعلها مع معاملات الري/القدرة الخاصة أعلى من النسبة بين القدرة العامة وتفاعلها مع معاملات الري/القدرة العامة لنسبة البروتين، نسبة الكربو هيدرات و نسبة الرماد ومحصول الحبوب/نبات. أظهرت كل من السلالات الأبوية P2 ، P1 و قدرة P5 P3 عامة على التألف موجبة و معنوية لصفة المقاومة للثغور و أظهرت كل من، P6 و P7 قدرة عامة على التألف موجبة و معنوية لصفة محصول الحبوب للنبات. أظهر الهجين P3 x P4 قدرة خاصة على التألف معنوية لصفة درجة حرارة الورقة، معدل النتح، صافي التمثيل الضوئي و نسبة الكربو هيدرات و الهجن P<sub>1</sub> x P<sub>5</sub> و P<sub>4</sub> x P<sub>6</sub> لصفة المقاومة للثغور، الهجن P<sub>4</sub> x P<sub>5</sub> و P<sub>5</sub> x P<sub>8</sub> الصفة المقاومة للثغور، الهجن P<sub>4</sub> x P<sub>5</sub> و لنسبة البروتين تحت ظروف الري الطبيعي (الكنترول)، الإجهاد والتحليل المشترك.
